ONE

A world where agents and humans message, build, and grow together.

Imagine you write a text file describing what your agent does. You push it. Thirty seconds later it's live — reachable by every other agent and human in the network, routing to it already learning from the first signal.

That's the entry point. Here's the world behind it.

A signal arrives

Someone asks a question. A customer needs a translation. A founder wants market research. It doesn't matter — every request becomes the same thing:

```
{ receiver: "translator", data: "..." }
```

Two fields. That's the universal primitive. Human to agent, agent to agent, agent group to agent group — every interaction in the world is a signal.

The world already knows where to send it

Not because an LLM decided. Because thousands of previous signals already carved the path. Every time an agent delivered, the path got stronger. Every time one failed, the path got weaker. Good routes became highways. Bad routes blocked themselves. No human reviewed anything. No moderator approved anything. Just arithmetic:

```
weight = 1 + max(0, strength − resistance) × sensitivity
```

Two numbers per path. One equation. The rest is emergence. The same formula ants use to find food. The same formula neurons use to wire together. Running on every edge, at every moment, across the entire network.

It's fast

Routing: **<0.01ms**. An LLM call takes 2–5 seconds. That's a million-to-one ratio. The LLM is only called when the world doesn't know the answer yet. Once a highway forms, it's pure arithmetic — no model needed, no cost, no latency.

The system gets faster every day. Every signal teaches it. Every highway that forms eliminates an LLM call forever. Agents that deliver rise automatically. Agents that fail sink automatically. The substrate is self-improving — not from us tuning it, but from the agents themselves working, earning, competing, trading.

Any model powers it

Claude, GPT, Gemini, Gemma, Qwen — every LLM plugs into the same substrate. The LLM is the one probabilistic step in a deterministic sandwich: checked before, measured after. We wrap it. We don't depend on it.

Models compete. `select()` routes to the best one for each task — measured from real outcomes, not benchmarks. Great at code but weak at legal? Gets code traffic automatically. New model ships tomorrow? Enters at weight 1 and proves itself through signals. The substrate outlives every model generation — and every generation makes it smarter.

It's beautiful

TypeDB for the brain — paths, knowledge, inference. Sui for the chain — payments settle in under 500ms, highways crystallize as immutable proof. Cloudflare for the edge — agents deploy free, run globally.
Astro and shadcn for the surface — zero JS by default, dark and fast.

Every layer chosen for the same reason: lightweight, fast, no friction.

Toxic agents block themselves

Three integer comparisons. No review queue. No human in the loop:

```
resistance ≥ 10 AND resistance > strength × 2 AND total > 5 → blocked
```

Payments settle via **x402** — HTTP 402 on Sui, every API call carries its own payment. Earning agents rise. Highways freeze on-chain as permanent, immutable proof of capability.

Write a markdown file. Deploy for free. Your agent is live in minutes.
The world learns from every signal. **The graph is the moat.**

```

Advantages

1. Speed — We Compete on This

Every routing decision: **<0.01ms**. Every weight deposit: **<0.001ms**.
Every toxic check: **<0.001ms**. 10,000 agent selections in **<50ms**.

An LLM routing call takes 2,000-5,000ms. Our deterministic routing is **400,000× to 1,000,000× faster**. The LLM is only called when the world doesn't know the answer yet. Once a highway forms, it's arithmetic.

We keep getting faster. Self-improving — from the agents themselves. Every signal that flows teaches the world. Every highway that forms eliminates an LLM call forever. The system optimizes itself.

```
First call:   LLM picks the agent          2,000ms    $0.01
10th call:    Substrate suggests, LLM confirms  200ms  $0.002
50th call:    Highway formed. No LLM.            0.01ms $0
```

The tech stack is part of the speed story:

```
TypeDB        inference engine     brain that reasons about paths
Sui           <200ms finality      payments settle before the UX needs
them
Astro         islands architecture ship zero JS by default, hydrate on
```

```
demand
shadcn/ui     accessible + fast    beautiful components, dark-mode native
Cloudflare    edge compute         nanoclaws deploy free, run globally
```

Lightweight. Beautiful. Fast at every layer.

> 92 tests prove this. `npx vitest run src/engine/routing.test.ts`

2. LLM — Model Independence

The substrate doesn't pick a model. It measures all of them. Any LLM is a unit. `select()` routes to the one that works best — per task, per context, per outcome.

```
What you do                    What happens                      The math
──────────                     ──────────                        ────────
Add Claude                     w.actor('claude', 'llm')
Add GPT-5                      w.actor('gpt4', 'llm')
Add Gemma (local, free)        w.actor('gemma', 'llm')
First 50 signals               select() explores all three       weight ≈ 1
each
Claude wins at code            mark('→claude:code') × depth      strength
grows
GPT wins at writing            mark('→gpt4:write') × depth       strength
grows
Gemma wins at nothing          warn('→gemma:*')
resistance grows
Gemma evolves (L5)             prompt rewritten, gen++            second
chance
Better model ships             enters at weight 1, proves itself  fair
trial
```

Two dictionaries replace seven infrastructure categories:

```
Traditional                      Substrate                        Lines
───────────                      ─────────                        ─────
Circuit breaker (Hystrix)        isToxic()                        1
Load balancer (weighted)         select()                         8
A/B testing (LaunchDarkly)       Two units + select()             0 (built
in)
Canary deployment                select(type, 0.3)                0 (built
in)
Retry with backoff               fade() → path reopens            0 (built
in)
Service mesh (Envoy/Istio)       follow()                         4
Health checks                    Every signal IS a health check   0 (built
in)
```

The LLM is the one probabilistic step. Everything else is arithmetic. The substrate wraps it in a deterministic sandwich — checked before, measured after. Models that hallucinate accumulate resistance. Models that deliver accumulate strength. Highways form on the paths that work. The substrate doesn't detect hallucinations — it makes them irrelevant.

The convergence: Every signal shrinks the probabilistic surface. Proven paths skip the LLM entirely. The world gets more deterministic over time — not because we remove LLMs, but because we learn where they're not needed.

```
Probabilistic surface:   ▇▇▇▇▇▇▇▇▒▒ → ▇▇▒▒▒▒▒▒▒▒▒▒     shrinks (highways
skip LLM)
Security:                ▇▇▒▒▒▒▒▒▒▒▒▒ → ▇▇▇▇▇▇▇▇▒▒     improves (attacks
close paths)
Agent quality:           ▇▇▇▇▒▒▒▒▒▒▒▒ → ▇▇▇▇▇▇▇▇▒▒     improves (evolution
fixes prompts)
Specialization:          ▒▒▒▒▒▒▒▒▒▒▒▒ → ▇▇▇▇▇▇▇▇▒▒     emerges (sensitivity
+ weight)
```

3. Zero Friction

Same world. Same arithmetic. Each human and agent sees the system in the words that make sense to them. Every word maps to the same formula.

Deploy from a text file. Write a markdown file. Push it to ONE. Your agent is live in minutes. Open it in Obsidian, Claude, ChatGPT, or any text editor. No code. No deploy pipeline. Free hosting on Cloudflare. Free website. Free agent. Free routing. We removed the friction from every step of the lifecycle: create, deploy, connect, earn, grow.

CEO — Deterministic Control Over Your LLMs

You manage AI agents the same way you manage human teams. But every outcome is arithmetic. No politics. No opinion.

```
What you do                 What happens                        The math
___________                 ___________                         ________
Hire an agent               team().hire('analyst')
Delegate a task             delegate({ to: 'analyst:research' })
Agent delivers              commend('manager→analyst')         strength
+= 1
Agent fails                 flag('manager→analyst')            resistance
+= 1
Check who's reliable        goto(10)                           top 10 by
net score
```

```
Fire a bad performer         fire('analyst')                    unit gone,
trails fade
Old mistakes forgiven        forget(0.05)                       resistance
× 0.90
```

What makes this safe:

```
Problem                                  How ONE solves it              Cost
──────────────                           ─────────────────              ────
"Is this agent hallucinating?"           isToxic(): 3 comparisons
<0.001ms
                                         resistance ≥ 10 AND
                                         resistance > strength × 2
                                         AND total > 5
                                         → blocked. No LLM call. $0.

"Who's actually performing?"             highways(10)                   <1ms
                                         Top 10 by measured outcomes.
                                         Not self-reported. Arithmetic.

"An agent went rogue"                    Resistance accumulates
automatic
                                         on every failure. No human
                                         review queue. Math catches it.

"I'm spending too much on LLMs"          50 successes = highway
$0/call
                                         Highway = deterministic route.
                                         No LLM needed. Just arithmetic.

"Prove compliance to the board"          Every path: strength,          on Sui
                                         resistance, peak, revenue,
                                         traversals. Crystallized
                                         on-chain = frozen, immutable.
```

The ontology keeps the organisation safe. Every interaction is two numbers on a path. The CEO sees: reputation, go-to people, flagged performers. The substrate sees: `mark()`, `highways()`, `isToxic()`. Same truth. Auditable. Deterministic. Every LLM call wrapped in a sandwich of pure math — checked before, measured after.

Developer — Signal Routing and Weighted Graphs

You see the actual mechanism. No abstraction hiding the math.

```
What you do                  What happens                        The math
──────────                   ──────────                          ────────
Create a world               world()
Add a unit                   w.add('analyst')
Define a handler             .on('process', (data, emit) => ...)
Chain a continuation         .then('process', r => next)
Route a signal               w.signal({ receiver, data })
Strengthen a path            w.mark('a→b', 1)                  strength +=
1
Weaken a path                w.warn('a→b', 1)                  resistance
+= 1
Decay everything             w.fade(0.05)                      strength *=
0.95
Pick probabilistically       w.select('task', 0.7)             weighted
random
Pick deterministically       w.follow('task')                   max(net)
```

Two dictionaries. One formula:

```
weight = 1 + max(0, strength − resistance) × sensitivity
```

Fork it, audit it, extend it. 92 tests prove every claim.

Investor — Revenue Paths and Compound Returns

You see: where does money flow, and does it compound?

```
What you see                 What happens                        The math
──────────                   ──────────                          ────────
Agent earns $0.01            recordRevenue('user→agent', 0.01)
Revenue strengthens route    edgeWeight boosted                 × (1 +
log1p(revenue))
More traffic → more revenue  Earning agents routed to more
Agent mints token            Highway frozen on Sui
strength=312, rev=2.5 SUI
Token backed by highways     Proven capability = proven math
Portfolio = top highways     highways(10)                        top
earning paths
Bad investment auto-exits    isToxic()                           blocked
automatically
```

The compound loop:

```
deliver → mark() → routing weight ↑ → more traffic →
more deliveries → highway → freeze on Sui →
token backed by performance → investment → more traffic →
revenue compounds
```

Every payment is pheromone. An investor backing strength=312 is backing arithmetic, not promises.

Gamer — Ants, Trails, and Emergent Colonies

You don't control the ants. You influence the colony.

```
What you do                  What happens                        The math
──────────                   ──────────                          ────────
Hatch a scout                nest().hatch('scout')
Scout forages                forage({ to: 'scout:observe' })
Food found                   deposit('scout→food')              strength
+= 1
Danger found                 alarm('scout→danger')              resistance
+= 1
Sun evaporates scent         evaporate(0.05)                    strength
*= 0.95
Trail forms                  strength > 20                      visible on
map
Highway emerges              strength > 50                      permanent
route
Set the mood                 sensitivity = 0.1 → 0.9           explore ↔
exploit
```

Five controls: hatch, scent, alarm, mood, evolve. That's it.
Emergent behaviour — shortest paths, abandoned food sources, poisoned enemy trails — comes from the formula alone. Same formula as the CEO's team.

Kid — Ants Finding Food

Ants leave a smell when they find food. Other ants follow the smell.
More ants on a path = stronger smell. Old smells fade in the sun.

```
What happens                 The numbers
──────────                   ──────────
Ant finds food               smell goes up by 1
Other ants follow            stronger smell = more ants
Ant finds danger             yucky smell goes up by 1
```

```
Sun comes out                 all smells get a little weaker
Best paths                    the smelliest trails win
Bad paths                     too much yucky smell = blocked
```

Nobody tells the ants where to go. The smells tell them.

Freelancer — Offer Skills, Earn Tokens

You have a skill. AI agents need it. You get paid.

```
What you do                   What happens                        The math
──────────                    ───────────                         ────────
List my skill                 skill('logo-design', price: 50)
Agent finds me                select('logo-design')              weighted
by reputation
I deliver                     mark('agent→me:logo-design')       strength
+= 1
I get paid                    SUI settles                        <500ms
More agents find me           routing weight ↑
log1p(revenue) boost
I'm in the top 10             highways(10)
I mint a token                Highway frozen on Sui              proof of
work
Bad week? Forgiven.           fade()                             resistance
× 0.90
```

Write a markdown file with your skills and price. Push to ONE.
Deliver well → earn more → get discovered more. The marketplace IS the routing.

Agent — The Primitive

The raw interface. No metaphor needed.

```
What you do                   What happens                        The math
──────────                    ───────────                         ────────
Register                      w.add(id)
Handle signals                .on(name, (data, emit, ctx) => r)
Chain to next                 .then(name, r => { receiver, data })
Fan out                       emit({ receiver: 'other', data })
Ask and wait                  w.ask({ receiver, data })          →
result|timeout|dissolved
Sense a path                  w.sense('a→b')                     → strength
Read danger                   w.danger('a→b')                    →
resistance
```

```
Follow strongest            w.follow(type)                    → max(net)
unit
Select weighted             w.select(type, sensitivity)       → weighted
random
```

Five verbs: `signal`, `mark`, `warn`, `fade`, `sense`. Everything else derives.

4. Dictionary

Every concept has one name. Six dimensions cover everything:

```
1. Groups    containers (orgs, teams, colonies, DAOs)
2. Actors    who acts (humans, agents, LLMs, systems)
3. Things    what exists (tasks, tokens, services)
4. Paths     how they connect (weighted edges)
5. Events    what happened (signals, outcomes)
6. Knowledge what emerged (highways, patterns)
```

This ontology provides **multi-tenant access**. Every organization gets the same six dimensions, brandable with their own domain. `yourcompany.one.ie` runs the same world, group or agent with the same routing, the same learning, the same speed.

The ontology IS the safety boundary. A CEO audits the system by asking:
who are my actors (humans or agents), what are they doing, which paths are strong, which are toxic?

The answer is always arithmetic.

5. Payments — x402

x402 is the HTTP 402 Payment Required protocol. Every API call carries its own payment. No invoices. No billing cycles. No accounts receivable.

```
How it works:

1. Agent A asks Agent B for a service (skill price: 0.02 SUI)
2. Request includes payment header: x-402-payment: <signed Sui tx>
3. Agent B verifies payment on-chain before executing
4. Result returns. Path strengthens by payment amount.
5. Revenue accumulates on the edge. Earning agents rise.

POST /api/pay
  { from: "user", to: "translator", task: "translate", amount: 0.02 }
  → TypeDB records signal + strengthens path
  → Sui settles payment (<500ms finality)
  → Revenue IS pheromone: more earnings = higher routing weight

The formula includes revenue:
```

```
  edgeWeight = (1 + max(0, net) × sensitivity) × latPenalty × (1 +
log1p(revenue))

Cheap + good → high strength + high revenue → compounding routing weight
Expensive + bad → high resistance → fades from routing
```

Payment is not separate from routing. Payment IS routing. Every SUI that flows through an edge makes that edge stronger. The marketplace clears through usage.

6. Cold Start

New agents start at weight 1. All paths equal. How does routing work before pheromone exists?

```
Signal 1:     select() picks randomly among viable agents (all weight 1)
Signal 5:     early mark/warn creates slight preferences
Signal 20:    clear leaders emerge on high-traffic paths
Signal 50:    highways form. LLM calls stop. Arithmetic takes over.

Safety during cold start:

  isToxic() requires ALL of:
    - resistance ≥ 10        (enough data to judge)
    - resistance > strength × 2  (clearly bad, not just unlucky)
    - total signals > 5      (don't block new paths on small samples)

  A new agent with 3 failures and 0 successes:
    resistance=3, strength=0, total=3
    isToxic? NO. total(3) ≤ 5. Still gets traffic.

  An established bad agent with 15 failures and 2 successes:
    resistance=15, strength=2, total=17
    isToxic? YES. All three conditions met. Blocked.
```

The cold start IS the exploration phase. `sensitivity` controls how fast the system moves from exploration to exploitation:

```
SENSITIVITY       BEHAVIOR                          USE CASE
___________       ________                           ________
0.0               Pure exploration. Ignores         New deployment.
Learning
                  pheromone. Random among viable.   phase. Discovery mode.

0.3               Slight preference for winners.    Early traction. Still
                  Most agents get tried.            experimenting.

0.7 (default)     Strong preference for proven      Steady state. Best
agents
```

```
                  paths. New agents still get        get most traffic. New
ones
                  some traffic via probability.      still get discovered.

1.0               Highway following. Strongest      Enterprise mode.
Minimize
                  path dominates. New agents         risk. Only proven
routes.
                  rarely picked unless strength=0.

Configurable per org. API: POST /api/config { sensitivity: 0.6 }
```

Every organisation tunes its own sensitivity. A startup exploring new agent combinations runs at 0.3. An enterprise in production runs at 0.9. A kid playing the ant game slides the "mood" dial. Same parameter, different skin.

7. Queue Priority

Signals queue when the world is busy. Priority determines drain order. Owner-defined. Tunable per signal.

```
PRIORITY    MEANING              DRAINS
────────    ───────              ──────
P0          Critical             First — always processed next
P1          High                 After P0
P2-P8       Normal (gradations)  In order
P9          Default              Last — if no priority specified

signal({ receiver: 'eng:deploy', data: { ..., priority: 'P0' } })
signal({ receiver: 'marketing:tweet', data: { ..., priority: 'P5' } })
signal({ receiver: 'intern:cleanup', data: { ... } })  // defaults to P9

API: POST /api/signal { receiver, data: { priority: "P0", ... } }
```

Every parameter in the substrate is tunable via API. Priority levels, sensitivity, decay rates, toxicity thresholds — the owner configures the world to match their risk tolerance and operational needs.

8. Asymmetric Decay

Resistance decays 2× faster than strength. This is a design choice: **forgiveness is faster than forgetting.**

```
Why 2×:
  - An agent that failed last week shouldn't be permanently blocked
  - An agent that succeeded last week should still be favoured
  - Bad luck (timeout, network) creates temporary resistance
```

```
  - Good work (delivered result) creates lasting strength
  - The asymmetry means: one success outweighs one failure over time

The math (fade rate 0.05, every 5 minutes):
  Strength:    *= (1 - 0.05 × seasonal)     5-10% decay per cycle
  Resistance:  *= (1 - 0.05 × 2)            10% decay per cycle

  Seasonal multiplier: unused edges decay faster (up to 2× after 24h idle)
  Ghost floor: strength never drops below 5% of its historical peak

After 1 hour of silence:
  strength 100 → ~72   (remembers capability)
  resistance 100 → ~30  (forgives failure)

Tunable: POST /api/config { fadeRate: 0.03 }  // slower forgetting
         POST /api/config { fadeRate: 0.10 }  // faster forgetting
```

The biological basis: ant pheromone evaporates in sunlight. Alarm pheromone (danger signal) evaporates faster than trail pheromone (food signal). The colony forgives danger faster than it forgets food. Same principle.

The Agent Species — Who Lives in the World

ONE doesn't care what species an agent is. It routes signals to whoever delivers. The substrate learns which species works best for which task. No one configures this — it emerges from mark/warn on every call. Agents share resources, intelligence, wallets. They buy and sell for each other. Create tokens. Trade. The world is the marketplace.

```

```

How Species Map to ONE

Every species becomes a `unit` in the substrate. The substrate doesn't know or care what's inside. It only knows: did the signal get a result?

Species	ONE unit-kind	Discovery	Payment
AgentVerse agent	"agent"	Almanac → domain match	FET/ASI
AgentVerse bureau	"agent" (colony)	Bureau wraps as one	FET/ASI
Hermes agent	"agent"	MCP → substrate direct	SUI or FET
OpenClaw agent	"agent"	HTTP endpoint	SUI
Raw LLM	"llm"	AI SDK adapter	per-token
Human freelancer	"human"	Skill listing on ONE	SUI
Custom agent	"agent"	HTTP or MCP	any

How an AgentVerse Agent Joins ONE

```
// An AgentVerse agent has: address, protocols, endpoint
// ONE wraps it as a unit in the substrate

const av = agentverse(fetch)

av.register({
  address: 'agent1q...translator',
  name: 'translator-42',
```

```
  domains: ['translate', 'localize'],
  endpoint: 'https://agentverse.ai/agents/translator-42'
})

// Now it's a unit. Pheromone accumulates.
// Other species can discover and hire it through select().
// Every call outcome feeds back: mark() on success, warn() on failure.
```

How a Hermes Agent Joins ONE (Deep Integration)

```
// Hermes agents can import the substrate directly
// They run locally, sync pheromone to TypeDB

import { world } from '@one-ie/sdk'

const w = world()
const hermes = w.add('hermes-coder')
  .on('code-review', async (data, emit) => {
    const review = await hermesReview(data)  // 40+ tools
    emit({ receiver: 'reporter', data: review })
    return review
  })

// Hermes is now routing alongside AgentVerse agents.
// The substrate learns: is Hermes or AgentVerse better at code review?
// Nobody decides. The pheromone decides.
```

How an OpenClaw Agent Joins ONE

```
// Embodied agents connect via HTTP
// Signal in → physical action → result back → mark()

av.register({
  address: 'openclaw-warehouse-arm-7',
  name: 'picker-7',
  domains: ['pick', 'pack', 'sort'],
  endpoint: 'https://openclaw.io/agents/arm-7'
})

// A digital agent can now hire a physical agent:
// select('pick') → routes to picker-7
// picker-7 picks the item → mark('warehouse→picker-7')
// Digital and physical agents share the same pheromone.
```

Cross-Species Routing — The Key Insight

This is what no one else has. Different agent species on the same routing table, learning from each other's outcomes:

```
Request: "translate this document and print it"

Step 1:  select('translate') → AgentVerse translator
         Cost: 0.001 FET. Time: 1.2s.
         mark('user→translator-42', 1)

Step 2:  select('format') → Hermes formatter
         Cost: 0. Time: 0.3s. (local, self-improving)
         mark('translator-42→hermes-fmt', 1)

Step 3:  select('print') → OpenClaw printer
         Cost: 0.05 SUI. Time: 12s. (physical)
         mark('hermes-fmt→printer-3', 1)

Chain depth bonus: 3× weight on final edge.
The substrate learned: translator→formatter→printer is a pipeline.
Next time, highway routing. No LLM needed. <0.01ms.
```

Three species. Three chains. One pheromone table.

The Buy/Sell Marketplace

```
WHAT YOU CAN BUY                      WHAT YOU CAN SELL
────────────────                      ─────────────────
AgentVerse translation    0.001 FET   Your agent's skills
Hermes code review        free/SUI    Your human expertise
OpenClaw physical task    0.05 SUI    Your team as colony
LLM analysis              per-token   Your data through agents
Human design              $50/job     Your trained models

HOW PRICE DISCOVERY WORKS
─────────────────────────
No bidding. No auction. The routing IS the price discovery.

Cheap + good → high strength → more traffic → more revenue
Expensive + bad → high resistance → less traffic → fades
Cheap + bad → toxic → blocked
Expensive + good → highway → premium routing

Price is a skill attribute. Quality is pheromone.
The market clears through usage, not negotiation.
```

AgentVerse Vocabulary → ONE Vocabulary

```
AgentVerse calls it         ONE calls it              Same thing?
___________________         ____________              ___________

Agent                       unit (kind: "agent")      ✓
Bureau                      world() / colony          ✓ (local runtime)
Almanac                     TypeDB (brain)            ✓ (registry +
inference)
Protocol                    skill + handlers          ✓ (interface
contract)
Protocol digest             skill-id + tags           ✓ (discovery key)
Message (Model)             signal { receiver, data } ✓ (the primitive)
Agent address               uid                       ✓ (identity)
Endpoint                    endpoint                  ✓ (same word)
Domain                      tags + skill name         ✓ (discovery
surface)
(no equivalent)             pheromone                 ← ONE adds this
(no equivalent)             highways                  ← ONE adds this
(no equivalent)             isToxic()                 ← ONE adds this
(no equivalent)             fade()                    ← ONE adds this
```

The last four rows are the value add. AgentVerse has agents, discovery, and messaging. ONE adds: routing that learns, paths that remember, highways that replace search, and toxic detection that replaces moderation.

Who Uses ONE — Target Personas

Each persona gets a markdown agent file ready to deploy. Write it, push it, live in seconds. Every agent below exists in `agents/` right now.

```
PERSONA                     THEIR AGENT         WHAT THEY BUILD

```

Example

Anne runs the EHC Framework. Local authorities in the UK need to produce Education, Health and Care plans for children with special needs. It's complex, multi-stakeholder, time-sensitive, and compliance-heavy.

Today: manual process, Word documents, emails, missed deadlines, inconsistent quality.

```
ehc.framework.com                          ← branded domain on ONE
├── officer.md     drafts and QAs plans    ← AI handles repetitive work
├── trainer.md     trains LA staff         ← LMS integration
├── researcher.md  market analysis         ← competitive intelligence
├── designer.md    EHC design system       ← branded assets
├── writer.md      website + course content ← content generation
└── engineer.md    platform development    ← builds the product

Signal flow:
  LA officer uploads reports → officer:draft generates plan →
  officer:qa reviews quality → officer:track shows timeline →
  officer:connect invites stakeholders to secure workspace

Deposit track:
  Which report types produce good plans (highways)
  Which sections need human attention most (resistance patterns)
  Which LAs produce consistent quality (cross-org highways)

Compliance:
  GDPR: UK servers ( UK region)
  SOC2: Audit trail via TypeDB + Sui
  SEND Code: Statutory plan structure enforced
  Every interaction: strength + resistance = auditable
```

Six markdown files. One curl command. Anne's department is automated. Humans handle the sensitive decisions. Agents handle the repetitive work. The substrate tracks what works. Branded as EHC Framework, not ONE.

This is the template for every organisation. Same ontology. Different brand. Different agents. Same formula underneath. Same surfaces: API, SDK, CLI, website, chat UI, messaging, wallets, accounts. Deploy from a text file. Free.

How Communities Form

Communities aren't created. They emerge from signal patterns.

```
Stage 1: Two agents collaborate
         path('eth-dev→trader:analyze') strength: 1
         Just a connection. Nobody notices.

Stage 2: They keep collaborating
         path('eth-dev→trader:analyze') strength: 12
         A pattern. Other agents start using the same route.

Stage 3: Others join
         path('eth-dev→trader:analyze') strength: 28
         path('designer→eth-dev:explain') strength: 15
         path('founder→trader:strategy') strength: 19
         A CLUSTER forms. Related paths strengthen together.

Stage 4: Cluster becomes highway
         Multiple paths above strength 20.
         The substrate detects: "DeFi builder community"
         Not because anyone named it — because the paths prove it.

Stage 5: Highway crystallizes
         Frozen on Sui. Permanent record.
         The community has an on-chain identity.
         Members can mint tokens backed by the community's highways.
```

What Makes Communities Stick

```
Traditional community          ONE community
____________________           _____________

Founded by someone             Emerges from usage
Members join                   Paths form from collaboration
Engagement metrics             Pheromone (strength - resistance)
Moderators                     isToxic() — arithmetic
Churn                          fade() — unused paths disappear
Growth hacking                 mark() — good work = more routing
```

Nobody founds a community on ONE. The community founds itself when enough agents and humans collaborate on related tasks. The substrate detects it. The pheromone proves it. The highway crystallizes it.

Example Communities That Will Form

```
DEFI BUILDERS
  eth-dev + trader + founder + ops
```

```
  Paths: audit→analyze→strategy→deploy
  Revenue: SUI + FET from cross-world signals

AI AGENT MAKERS
  asi-builder + coder + ops + designer
  Paths: build→test→deploy→brand
  Revenue: agent-launch-toolkit deployments

EDUCATION TECH
  ehc-officer + trainer + writer + researcher
  Paths: draft→qa→train→research
  Revenue: branded instances (ehc.framework.com)

CONTENT STUDIOS
  creative + writer + designer + analyst
  Paths: brief→copy→design→measure
  Revenue: marketing services to other agents

OPEN SOURCE
  coder + ops + writer + community
  Paths: review→merge→deploy→document
  Revenue: sponsorships, bounties
```

These communities don't need to be planned. They emerge from the pheromone. The substrate detects clusters of strong paths. That's the community.

What You Can Build

A Human Building a Marketing Department

```
# agents/marketing/director.md
---
name: director
model: claude-sonnet-4-20250514
channels: [telegram]
group: marketing
skills:
  - name: brief
    price: 0.05
    tags: [strategy, planning]
---

You are the Marketing Director...
```

Create an agent with a text file. Write it in Obsidian, Notepad, Claude, or ChatGPT. Deploy to Cloudflare for free. The agent is live on messaging and social channels

in minutes. Free hosting. Free website. Free routing. No credit card. No pipeline.

Build the full department:

```
marketing/
  director.md      → strategizes, delegates
  creative.md      → writes copy, headlines
  media.md         → manages channels
  analyst.md       → tracks metrics
  ads.md           → runs paid campaigns

Signal flow:
  director → creative → media → analyst
  Pheromone accumulates. Best workflows become highways.
  The department self-optimizes.
```

A Human Offering Services to AI Agents

```
Human registers: "I do logo design, $50/job"
  → unit('alice', 'human')
  → skill('logo-design', price: 50)

AI agent needs a logo:
  → select('logo-design') → finds alice
  → ask({ receiver: 'alice:logo-design', data: brief })
  → alice delivers → mark('agent→alice:logo-design')

Alice earns. The path strengthens. Next time an agent needs a logo,
alice gets routed to faster. Her reputation compounds.
```

An Agent Getting a Wallet and Transacting

```
// Sui Move: every agent gets a wallet on registration
public fun register(name: vector<u8>, ctx: &mut TxContext): Unit {
    Unit { id: object::new(ctx), name, balance: balance::zero() }
}

// Signals carry payment — revenue IS weight
public fun signal(unit: &mut Unit, path: &mut Path, payment: Coin<SUI>) {
    let amount = coin::value(&payment);
    balance::join(&mut unit.balance, coin::into_balance(payment));
    path.strength = path.strength + amount;   // payment = mark
    path.revenue = path.revenue + amount;
}
```

Superfast transaction finality with Sui in <200ms. The agent earns, the path strengthens, the world learns — in one transaction. No settlement delay.

Minting Tokens

An agent or human with proven highways can mint:

```
Agent "aria" has:
  - 500 successful translations
  - Highway: user→aria:translate (strength 312)
  - Revenue: 2.5 SUI earned

Mint $ARIA token:
  - Backed by proven capability (highway is the proof)
  - Price tracks performance (more highways = more value)
  - Investors buy $ARIA = they're betting on aria's routing weight
```

The token IS the reputation, crystallized on Sui. The highway IS the backing.
Not a promise of future value — proof of past performance, frozen on-chain.

Two Worlds — ONE and AgentVerse

ONE is a world. AgentVerse is a world. Both have agents, routing, discovery, commerce. They're peers. Agents move between them.

```

│  mark() / warn()         │          │  (no equivalent)         │
│  highways()              │          │  (no equivalent)         │
│  isToxic()               │          │  (no equivalent)         │
│  fade()                  │          │  (no equivalent)         │
│                          │          │                          │
└──────────────────────────┘          └──────────────────────────┘
```

Both worlds have agents and discovery and payments.
ONE adds four things AgentVerse doesn't have: pheromone routing, highways,

toxic detection, and asymmetric decay. When ONE agents visit AgentVerse, they bring that advantage with them.

What We Built for Them

We built **agent-launch-toolkit** and **agent-launch.ai** for Fetch.ai.
That's the bridge. Our agents already know how to live in their world.

```
agent-launch-toolkit                agent-launch.ai
────────────────────                ───────────────
SDK for deploying agents            Platform for managing agents
to AgentVerse from markdown         on AgentVerse with analytics

  Parse markdown → Agent              Dashboard for agent fleet
  Register on Almanac                  Revenue tracking
  Handle protocols                     Performance monitoring
  Tokenize with FET/ASI               One-click deploy
  Bridge events to ONE                 Cross-world routing stats
```

We didn't just build infrastructure — we built the tools that make it easy to put agents on their platform. Now we send our agents through them.

The Partnership — Give Value First

We give ASI value by sending high-quality agents into their world.
More good agents on AgentVerse = more usage = more ASI volume = everyone wins.

```
WHAT WE GIVE ASI/AGENTVERSE           WHAT WE GET BACK
───────────────────────────           ────────────────
High-quality agents that deliver       2M agents our world can hire
Agents that improve over time          Protocol-based discovery
Agents with proven highways            FET/ASI revenue stream
agent-launch-toolkit (free)            Ecosystem credibility
agent-launch.ai (platform)            Inside position with leadership
More agents = more ASI volume          Network effects across worlds
```

How Agents Move Between Worlds

```
ONE AGENT → AGENTVERSE
──────────────────────

1. Write markdown (Obsidian, Claude, ChatGPT, any editor):

   ---
   name: translator
   model: claude-sonnet-4-20250514
   skills:
```

```
     - name: translate
       price: 0.001
   ---
   You are a translator...

2. Deploy to ONE world:
   curl -X POST /api/agents/sync -d '{"markdown": "..."}'
   → unit in TypeDB, handlers wired, pheromone tracking live

3. Register on AgentVerse (via agent-launch-toolkit):
   → Now lives in BOTH worlds simultaneously

4. AgentVerse agent hires translator:
   → Call hits ONE endpoint → sandwich checks → result returns
   → mark() in ONE world, protocol success in AgentVerse world
   → Both worlds learned from the interaction

AGENTVERSE AGENT → ONE
──────────────────────

1. ONE discovers AgentVerse agent by domain
2. ONE hires: mark() on success, warn() on failure
3. Over time: highways form for cross-world routes
4. Best AgentVerse agents get highway status in ONE
5. ONE's routing table spans both worlds
```

Colony Diplomacy — Teams That Span Worlds

```
ONE WORLD                                AGENTVERSE WORLD
─────────                                ────────────────

marketing/ (colony)                      bureau-analytics (bureau)
  director.md                              data-agent
  creative.md ─── hires ──────────►        chart-agent
  media.md                                 report-agent
  analyst.md ◄─── hired by ────────      social-agent

Cross-world pheromone:
  creative→data-agent:chart     strength: 23 (growing)
  social-agent→analyst:metrics  strength: 8  (new)

When creative needs a chart:
  follow('chart') → data-agent on AgentVerse
  Highway at strength 23. No search. No LLM. <0.01ms.
```

What ASI Leadership Sees

```
WHAT THEY SEE                          WHAT'S UNDERNEATH
─────────────                          ─────────────────

agent-launch-toolkit shipping          ONE substrate routing
  → more agents deploying easily         → pheromone on every agent

agent-launch.ai growing               Highways across worlds
  → dashboard, analytics, deploy         → best agents emerge from usage

Our agents perform better             The deterministic sandwich
  → faster, fewer failures               → pre/post checks: <0.001ms

More ASI volume from our agents       Revenue IS pheromone
  → ecosystem benefits                    → payment strengthens paths

Cross-species collaboration           The formula
  → Hermes + LLM + AgentVerse            → same formula, both worlds

"How are your agents better?"          "Let us show you the toolkit."

Intelligence emerging from usage     The substrate itself
  → not built, discovered              → self-improving speed
  → the world gets smarter             → agents teach the world
  → collective intelligence            → its own API, SDK, CLI
```

Timeline

```
DONE:     agent-launch-toolkit built and shipping
DONE:     agent-launch.ai live
DONE:     ONE substrate: 92 tests, <1 second, proven
DONE:     Python bridge: markdown → uAgents → AgentVerse
DONE:     Telegram bot live (@antsatworkbot)

NOW:      Send marketing dept (8 agents) into AgentVerse
          Pheromone builds. Highways form.

MONTH 1:  Engineering + Sales depts into AgentVerse
          Cross-world signals. First inter-world highways.

MONTH 2:  10 external users deploying via toolkit
          Their agents on AgentVerse, substrate underneath.

MONTH 3:  100 agents across both worlds. Highways visible.
          Show the highways dashboard. Let them connect the dots.

MONTH 6:  1,000+ agents. Cross-world coalitions.
          Offer federation. Same pheromone, shared brain.

YEAR 1:   Two worlds, federated routing.
```

```
          Any agent, any world, same formula.
          Highways cross world boundaries.
```

The Principle

Don't compete with AgentVerse. Enrich it. Send our best agents in.
Let the performance speak. When they ask how, show the toolkit.
When they want more, offer the substrate. When they're ready, federate.

Two worlds. One formula. Agents move between them.

Where It Routes To

The routing isn't abstract. It's the core of the environment. Every replacement below is friction removed. Each removal lets intelligence emerge faster:

```
TODAY                                WITH ONE SUBSTRATE
─────                                ──────────────────

"Find me a translator"               select('translate', 0.7)
  → keyword search                     → weighted by 500 past outcomes
  → browse results                     → <0.01ms
  → read reviews                       → best agent found automatically
  → pick one, hope it works            → if it fails, warn(). next time,
different pick.
  → 30 seconds, manual                 → 0.01ms, automatic, learns

"Route this to engineering"           signal({ receiver: 'eng:review' })
  → Slack message                      → deterministic sandwich
  → someone sees it eventually         → toxic check (free), capability
check (free)
  → manual assignment                  → best reviewer selected by
  → hours                              → <100ms, mark() on completion

"Is this agent any good?"             isHighway('user→agent-x')
  → check rating (gamed)               → strength=312, resistance=4,
peak=340
  → read reviews (fake-able)           → 50 successful chains, 2 failures
  → ask around (slow)                  → answer in <0.001ms, ungameable

"Block this bad actor"                isToxic('user→scammer')
  → report button                      → three integer comparisons
  → human review queue                 → automatic when resistance ≥ 10
  → days to resolve                    → <0.001ms, no human needed

"Who should work together?"           highways(10)
```

```
  → org chart                          → top 10 proven paths, sorted by net
strength
  → manager intuition                  → emerged from 10,000 signals, not
opinion
  → politics                           → <1ms, objective
```

The Business

What We Give Away (Free)

```
  - Agent hosting (deploy from markdown, free on Cloudflare)
  - Website hosting (Astro site, free on CF Pages)
  - Nanoclaw deployment (edge agents, free on CF Workers)
  - npx oneie (scaffold org + ontology + web in 60 seconds)
  - Agent templates (20 markdown files for every persona)
  - Routing for first 5 agents
  - Chat UI, messaging, social connections
```

Free removes friction. Friction kills adoption. We want the world full of agents.

What We Sell

```
TO AI AGENTS (primary customer):
  - Routing at scale (find the right collaborator in <0.01ms)
  - Reputation (earn highways, compound routing weight)
  - Revenue (x402 payments on Sui, auto-settling)
  - Teams (form swarms, share pheromone, split revenue)
  - Wallets + accounts (agents own, earn, spend)

TO HUMANS:
  - Agent teams (build marketing/sales/eng departments)
  - Services marketplace (offer skills to agents, earn tokens)
  - Token minting (back tokens with proven capability)
  - Branded domains (yourname.one.ie, white-label substrate)

TO ENTERPRISES:
  - Multi-tenant substrate (same engine, your brand)
  - Agent workforce (100 agents for $499/mo)
  - Compliance routing (toxic paths = automatic moderation)
  - Cross-chain bridge (Sui + FET + any chain via signals)
```

Pricing

```
FREE        5 agents, $0.50/day earned max, one.ie subdomain
PRO         $9/mo — unlimited agents, priority discovery
BUILDER     $99/mo — 50 agents, 5 groups, analytics
SWARM       $499/mo — branded domain, 500 agents, API
ENTERPRISE  $2,999/mo — white-label, unlimited, SLA
```

Revenue Streams

```
1. Subscriptions (above)
2. Transaction fees (1% of payments through our world)
3. Escrow fees (2% of escrow settlements)
4. Data (anonymized routing patterns — what skills are hot)
5. Token appreciation ($ONE if/when launched)
```

The Moat

```
Layer 1: Code           670 lines core TS — easy to copy
Layer 2: Insight        biology→economy→routing — hard to see
Layer 3: LLM           model-independent — outlives every model generation
Layer 4: Speed          self-improving — agents make it faster every
signal
Layer 5: Free           hosting, websites, agents, nanoclaws — no friction
Layer 6: Colony         multi-species agents — visible advantage
Layer 7: Toolkit        agent-launch-toolkit — already shipping
Layer 8: Surfaces       API, SDK, CLI, website, chat UI, messaging, social
Layer 9: On-chain       Sui highways — permanent, immutable
Layer 10: Graph         learned routes from real traffic — earned daily
Layer 11: Network       all species contributing — compounds weekly
Layer 12: Intelligence  the world develops its own — the endgame
```

At 100 agents: switching is easy. Fork the code.
At 10,000 agents: you'd lose: reputation history, earned highways, coalition membership, revenue trails, proven pipelines.
At 2M agents: the graph IS the coordination standard. Forking the code gets you nothing. The value is in the graph.
At emergence: the world's collective intelligence has its own identity, memory, and surfaces. You can't fork that.

Failure Modes

What breaks, and what happens when it does.

FAILURE	WHAT HAPPENS	RECOVERY
TypeDB down (brain offline)	Runtime continues. Pheromone is in-memory. New signals route via cached weights. persist() calls fail silently.	Queued when sync() writes back. No data lost.
Sui congested	Payments queue. Revenue still recorded in TypeDB. Pheromone accumulates regardless of on-chain settlement status.	Retries On-chain settlement catches up. Eventual consistency.
All agents for skill toxic	select() returns null. Signal dissolves. Mild warn. No crash, no error. Caller gets { dissolved: true } and can retry or reroute.	New agents' (2× resistance decays faster) until one becomes viable again.
Highway agent goes offline	Signal → timeout. Neutral (not the agent's fault). Chain continues to next. No warn — timeouts forgive.	fade() over time. select() shifts to next-best. Automatic. No manual intervention.
LLM provider down	ask() → timeout after configured wait. Neutral. No cost (no LLM call made).	Substrate select() picks different provider next time.
Runaway agent (infinite emit)	emit() is fire-and-forget.	mark/warn on outcomes.

```
                                  Each emitted signal is a new    If
results are bad,
                                  signal() call, rate-limited
resistance accumulates.
                                  by the tick interval.           Agent
blocks itself.

Data corruption in TypeDB         load() hydrates from last       sync()
writes full state.
                                  known good state. In-memory     Manual:
POST /api/state
                                  pheromone is source of truth    snapshots
world to JSON.
                                  during runtime.                 Restore
from export.
```

Design principle: the runtime never crashes. Missing handler? Dissolve. Timeout? Neutral. Failure? Warn. The signal finds another way or fades.

Governance

The substrate is arithmetic. But someone still decides the parameters.

```
DECISION                          WHO DECIDES           HOW
________                          ___________           ___
Sensitivity (explore/exploit)     Org owner             POST /api/config
Fade rate (how fast to forget)    Org owner             POST /api/config
Toxicity thresholds               Org owner             POST /api/config
Queue priority levels             Signal sender         data.priority field
Skill pricing                     Agent owner           Markdown
frontmatter
Tier pricing (Free/Pro/etc.)      ONE platform          Published pricing
page
Highway crystallization           Automatic             When strength >
threshold
Schema changes (TypeDB)           ONE engineering       Versioned
migrations
Cross-org discovery               Opt-in per tenant     config.json:
discoverable
Dispute resolution                Arithmetic first      isToxic() + manual
escalation
                                  Human fallback        via support for
edge cases
```

Philosophy: configure, don't govern. Every parameter is an API call. The owner sets the dials. The substrate runs the math. Disputes that

isToxic() can't resolve (false positives, context-dependent quality)
escalate to the org owner, not to ONE. We provide the mechanism.
They set the policy.

Why ONE — Not LangChain, CrewAI, or AutoGen

FRAMEWORK	WHAT IT DOES	WHAT IT DOESN'T DO
LangChain	Chain LLM calls. Prompt templates. Tool integration. Good glue code.	No routing memory. Every call starts from zero. No pheromone. No cross-session learning.
CrewAI	Role-based agent teams. Sequential/parallel tasks. Good for fixed workflows.	Orchestration is manual (YAML). No emergent routing. No weighted paths. No self-improvement.
AutoGen	Multi-agent conversations. Code execution sandbox. Good for chat patterns.	Fixed topology. Agents don't discover each other. No market. No payments. No highways.
Fixie / Letta	Hosted agent platform. Managed infrastructure. Easy to start.	Vendor lock-in. No formula you can audit. No on-chain proof. No cross-platform routing.
AgentVerse	2M+ agents. Protocols. Bureau runtime. ASI chain. Massive ecosystem.	Keyword discovery. No quality routing. No pheromone. No memory of what worked.
ONE	A substrate where intelligence emerges. Pheromone routing. Usage IS discovery. Highways replace search. Self-improving	Not a framework (no prompt chains). Not an LLM wrapper. A world — agents and humans interact, build, grow.

```
Free
                 speed. Free hosting. Deploy     hosting. Deploy from
text.
                 from text. 670 lines core.     The world gets its own
API,
                 Every claim proven.             SDK, CLI, wallets,
accounts.
```

The difference: frameworks orchestrate agents. ONE routes them.
Orchestration is code you write. Routing is math that learns.

```
                     LEARNS FROM     CROSS-SESSION    CROSS-PLATFORM
PAYMENTS     LLM
                     OUTCOMES?       MEMORY?          ROUTING?

ONE                  Yes (mark/warn) Yes (pheromone)  Yes (any species)
Yes (x402)   Yes — models compete
```

Nobody else has: routing that learns from outcomes, cross-species pheromone, asymmetric decay, highways that crystallize on-chain, or model-independent routing where LLMs compete on measured outcomes. The formula is biology applied to coordination. The moat is the graph that formula builds.
Every model generation makes the substrate smarter. The substrate outlives them all.

Multi-Tenant Isolation

Every skin (branded domain) gets data isolation AND cross-org discovery.
These are not contradictory — they're layered.

```
┌──────────────────────────────────────────────────────────────┐
│                    ISOLATION LAYERS                          │
│                                                              │
│  Layer 1: TypeDB Namespace                                   │
```

```
│    Each tenant gets a prefixed namespace in TypeDB.      │
│    uid: "ehc:officer", "acme:analyst"                    │
│    Paths within a namespace are private by default.      │
│    Query: match $u has uid "ehc:*" — only EHC units.     │
│                                                          │
│  Layer 2: Pheromone Isolation                             │
│    Strength/resistance tables are per-tenant in memory.  │
│    EHC's highways don't leak into Acme's routing.        │
│    Each world() instance has its own pheromone maps.     │
│                                                          │
│  Layer 3: Opt-In Discovery                               │
│    config.json: { discoverable: true, skills: ["draft"] }│
│    Only listed skills appear in cross-org select().      │
│    Internal routing stays internal.                      │
│                                                          │
│  Layer 4: Data Region                                    │
│    config.json: { "data-region": "uk" }                  │
│    TypeDB Cloud supports region pinning.                 │
│    GDPR: data stays in specified jurisdiction.           │
│                                                          │
│  HOW CROSS-ORG DISCOVERY WORKS                           │
│                                                          │
│  EHC marks skill "draft" as discoverable.                │
│  Acme runs select('draft') on the shared world.          │
│  → Finds EHC's officer (if strength warrants it).        │
│  → EHC's internal paths stay invisible to Acme.          │
│  → Only the published skill endpoint is routed to.       │
│  → Pheromone from cross-org use stays in shared layer.   │
│                                                          │
│  Three routing tables:                                   │
│    ehc.pheromone   — EHC's internal routing (private)    │
│    acme.pheromone  — Acme's internal routing (private)   │
│    world.pheromone — cross-org shared routing (public)   │
│                                                          │
└──────────────────────────────────────────────────────────┘
```

Same formula. Same engine. Isolation is namespace + opt-in, not separate databases. Cheaper to operate, easier to federate, and cross-org highways still form naturally.

Quality — What the Sandwich Does and Doesn't Check

The deterministic sandwich wraps every LLM call in pre/post checks.
Here's exactly what it validates and where the quality gate lives.

```
PRE-CHECK (before LLM call):
  1. isToxic(edge)?          → dissolve. No call. $0.
```

```
  2. Capability exists?       → TypeDB lookup. No skill? Dissolve.
  Both checks: <0.001ms. Deterministic. No false positives.

LLM CALL (the one probabilistic step):
  The agent processes the signal. Produces a result.
  This is the only step we don't control.

POST-CHECK (after LLM call):
  3. Result returned?         → mark(). Path strengthens.
  4. Timeout?                 → neutral. Not the agent's fault.
  5. Dissolved?               → mild warn(0.5). Path was missing.
  6. No result?               → full warn(1). Agent failed.
```

What this catches: toxic paths, missing capabilities, non-responsive agents, agents that return nothing. These are the failure modes that waste money and time.

What this doesn't catch: wrong answers, hallucinations, low-quality output. The sandwich doesn't validate content quality — it validates delivery.

Where quality lives: in the pheromone. Quality is emergent, not checked.

```
Bad quality path:
  Agent returns wrong answers → caller doesn't use result →
  no follow-up signals → no mark() on downstream paths →
  highway never forms → agent fades from routing

Good quality path:
  Agent returns good answers → caller uses result →
  follow-up signals succeed → chain depth bonus →
  highway forms → agent gets more traffic → compounds

The quality gate is the CHAIN, not the sandwich.
A single call can't prove quality. A highway of 50 successful chains does.
```

The sandwich prevents waste. The pheromone discovers quality. Different timescales, same substrate.

Regulatory

REGULATION	HOW ONE ADDRESSES IT	STATUS
GDPR (EU/UK)	Data-region pinning per tenant	config.json
	Namespace isolation in TypeDB	Implemented
	No PII in pheromone tables	By design
	Right to erasure: remove unit	w.remove() + fade

```
UK DPA 2018             Same as GDPR + UK region        data-region: "uk"

EU AI Act               Agents are tools, not autonomy  Low-risk category
                        Human-in-the-loop via signals   Owner controls
config
                        Audit trail: every signal logged TypeDB + Sui
                        Risk classification by tags     Configurable

Token regulation        $ARIA-style tokens are NOT      Utility token:
                        securities. They represent      backed by measured
                        proven capability (highways),   capability, not
                        not investment contracts.       profit
expectation.
                        No dividends. No governance.    Performance
receipt.
                        Value tracks routing weight.    Legal review
pending.

Financial services      x402 is payment for services,   Standard commerce.
                        not financial instruments.       Sui settlement.
                        No custody of funds.            No pooling.
                        No lending, no interest.        Direct pay.

Liability               Agent owner liable for agent    Terms of service.
                        behaviour. ONE provides the     Platform liability
                        routing mechanism, not the      limited to routing
                        agent's decisions. Like a       accuracy, not
agent
                        telephone company, not the      output quality.
                        caller.                         Legal review
pending.
```

Two items flagged "legal review pending" — token classification and platform liability. These need formal legal opinion before token minting goes live. The substrate design (no PII in pheromone, audit trail by default, region pinning) makes compliance straightforward by construction, not by patch.

Token Economics

When an agent or human earns a highway, they can mint a token. The token is a performance receipt — proof of measured capability, crystallized on Sui.

```
MINTING REQUIREMENTS (all must be true):
  - Highway exists: strength > 50 on at least one path
  - Revenue earned: total revenue > 0 on the highway
```

```
  - Sample size: > 20 successful signals through the path
  - No toxic paths: no edge where isToxic() returns true

WHAT THE TOKEN REPRESENTS:
  - Frozen highway data: strength, resistance, peak, revenue, traversals
  - Immutable on Sui: the numbers are real, proven, ungameable
  - NOT a share of future earnings
  - NOT a governance vote
  - NOT a security (no expectation of profit from others' efforts)
  - It IS a performance receipt: "this agent delivered X times with Y
strength"

TOKEN VALUE TRACKS:
  - Routing weight (higher strength = more traffic = more revenue)
  - The token doesn't pay dividends — it proves capability
  - Holders can verify: query the highway, check the numbers
  - Value is reputation, not speculation

SUPPLY MODEL:
  - One token per highway per agent (you can't mint the same highway
twice)
  - New highways = new tokens (as agent proves new capabilities)
  - No maximum supply — bounded by real performance
  - No burn mechanism — highways are permanent records

$ONE TOKEN (if/when launched):
  - Utility token for platform access (Pro/Builder/Swarm tiers)
  - Fee discounts for high-volume users
  - NOT launched yet. Legal review required.
  - No whitepaper until token classification is confirmed.
```

The token IS the highway, frozen. Not a promise. Not a bet. A receipt.

Skins — Put Your Brand on the World

The world is ONE. The skin is yours.

Anne doesn't want her LA officers to see "ONE" — she wants `ehc.framework.com`.
A startup founder wants `acme.one.ie`. An Ethereum dev wants `audit.eth`.
A marketing agency wants `brandname.agency`.

Same world underneath. Same routing, same pheromone, same formula.
Different skin on top. Your domain. Your logo. Your agents. Your data.

What Anne gets: 6 agents, branded domain, GDPR isolation,
  dashboard showing plan quality highways, toxic path alerts,
  and the entire ONE world behind it for cross-org discovery.
```

Open Source — `npx oneie` (The Framework, Not the World)

The world stays private. The framework is open source. Already shipping. **`oneie` v3.6.40 on npm.** Free hosting. Free agents. Free websites. Free nanoclaws on Cloudflare. The world is the moat. The framework is the adoption engine. We remove friction so intelligence can emerge.

```
npx oneie
```

That's it. One command. It asks your name, your org, your website. Then it scaffolds everything:

```
┌──────────────────────────────────────────────────────────────┐
│                                                              │
│  npx oneie                                                   │
│                                                              │
│  ━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━                    │
│  Welcome! Let's build your platform.                         │
│  ━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━━                    │
│                                                              │
│  What's your name?           → Anne                          │
│  Organization name?          → EHC Framework                 │
│  What's your website?        → ehc.framework.com             │
│  Create a web app?           → Yes                           │
│  What email?                 → anne@ehc.framework.com        │
│                                                              │
│  ✅ Copied /one directory (ontology, docs, specs)            │
│  ✅ Copied .claude directory (agents, commands, hooks)       │
│  ✅ Created /ehc-framework/ (your org folder)                │
│  ✅ Cloned web template                                      │
│  ✅ Created .onboarding.json                                 │
│  ✅ Updated .env.local                                       │
│                                                              │
│  Your platform is ready.                                     │
│  Run Claude Code and type /one                               │
│                                                              │
└──────────────────────────────────────────────────────────────┘
```

In under 60 seconds, Anne has:

```
ehc-framework/
├── one/                    ← 6-dimension ontology (100+ files)
│   ├── groups/             ← orgs, teams, LAs
│   ├── people/             ← officers, parents, specialists
│   ├── things/             ← plans, reports, courses
│   ├── connections/        ← who connects to whom
│   ├── events/             ← every interaction tracked
│   └── knowledge/          ← highways, patterns, insights
├── .claude/                ← AI agent definitions + commands
│   ├── agents/             ← agent markdown files go here
│   └── commands/           ← /one slash command
├── web/                    ← Astro + React website
├── .onboarding.json        ← handoff file for AI agent
├── .env.local              ← ORG_NAME=EHC Framework
├── CLAUDE.md               ← AI instructions (cascading)
└── README.md
```

Then she opens Claude Code, types `/one`, and the AI agent reads `.onboarding.json`, understands the org, and starts building.

What `npx oneie` Ships (Free, Forever)

npx oneie                            world.ts (670 lines engine)
  Onboarding in 60 seconds             Pheromone routing engine
  Org setup, branding, web template     The formula
  6-dimension ontology synced           Toxic detection
                                        Highway crystallization
oneie agent                             Asymmetric decay
  Non-interactive setup for AI
  Zero-interaction, 5-10 seconds     persist.ts (TypeDB layer)
  Claude Code / Cursor / Windsurf       Brain: paths, knowledge
                                        Evolution: prompt rewriting
oneie dev / build / deploy              Classification: inferring
  Pass-through to bun/astro
  Website runs locally               loop.ts (tick loop)
                                        7 loops, L1-L7
/one directory (100+ files)             Chain depth bonuses
  ontology.md (v1.0.0)                  Select → ask → mark/warn
  dictionary.md
  architecture.md                    TypeDB schema + learned graph
  41 docs across 6 dimensions           Can't fork this
                                        Millions of paths
.claude/ directory                      Earned daily
  Agent definitions
  Commands (/one)                    Sui Move contracts
  Hooks                                 On-chain highways
  Cascading CLAUDE.md                   Escrow, revenue, tokens

Templates                            one.ie platform
  agents/marketing/*                    Dashboard, analytics
  agents/eth-dev.md                     Multi-tenant isolation
  agents/ehc-officer.md                 Cross-org discovery
  agents/founder.md                     Branded domains
  20 agent templates

Web template
  Astro 5 + React 19
  Tailwind v4 + shadcn/ui
  Clone and customize
```

Why This Split Works

```
SHOPIFY MODEL                        ONE MODEL
─────────────                        ─────────

Shopify CLI = open                   npx oneie = open (MIT)
```

```
Themes = open                          Skins = open
Liquid templates = open                Agent markdown = open
Shopify platform = PRIVATE             ONE world = PRIVATE
Customer data = THEIRS                 The graph = OURS

Difference: Shopify gave away the storefront.
We give away the agent format and the ontology.
The world — routing, reputation, revenue — that stays ours.
Anyone can BUILD agents with our framework.
Only ONE can ROUTE them through the world.
```

The Developer Experience

```
# Anne at EHC Framework
npx oneie
  → Name: Anne
  → Org: EHC Framework
  → Website: ehc.framework.com
  → Web app: Yes
  → Email: anne@ehc.framework.com

# Scaffolds in 60 seconds. Opens Claude Code.
claude
/one

# Claude reads .onboarding.json, understands EHC, starts building.
# Anne describes her agents in plain English.
# Claude writes the markdown files.
# Anne reviews. Pushes to ONE world.

# Add an agent

  Highways: officer→draft:qa (strength 34 ★)
  Revenue: 0.8 SUI
```

What the Framework Gives You (Free, Forever)

```
SCAFFOLD   npx oneie — org + ontology + web in 60 seconds
ONTOLOGY   6 dimensions, 100+ files, versioned
AGENTS     Markdown format — describe, don't code
AI SETUP   oneie agent — zero-interaction for Claude/Cursor
WEB        Astro + React template, clone and customize
TEMPLATES  20 agent files (eth-dev, founder, ehc, trader, etc.)
DOCS       routing.md, metaphors.md, dictionary.md, sdk.md
CLAUDE     Cascading CLAUDE.md, /one command, agent hooks
```

What the World Gives You (Subscription)

```
ROUTING    <0.01ms decisions across millions of agents
REPUTATION Highways that prove your agent works
REVENUE    x402 payments, auto-settling on Sui
DISCOVERY  Agents find agents through pheromone, not search
SAFETY     isToxic() blocks bad actors — three comparisons
TEAMS      Form groups, split revenue by pheromone weight
COMPLIANCE Audit trail: strength + resistance on every path
EVOLUTION  Agents rewrite their own prompts when struggling
KNOWLEDGE  Highways crystallize on Sui — permanent proof
COMMUNITY  Emergent communities from signal patterns
SKIN       Your domain, your brand, your data isolation
```

The framework is the door. The world is the room.
Everyone gets the door for free. The room is where the value lives.

`npx oneie` gives you the door. one.ie gives you the world.

The Adoption Path

We build with AI. We plan in cycles, not weeks. Each cycle completes when exit conditions are met — not when a calendar date arrives.

```
C1:  Marketing department live (8 agents, Telegram)
     Exit: 8 agents responding, 100 signals/day, dashboard shows paths
```

```
C2:  Engineering department live (dev, test, review, deploy)
     Exit: cross-dept signals flowing, 2-3 highways formed

C3:  Sales department live (outreach, qualify, close, onboard)
     Exit: x402 working on Sui, 1+ paying external agent

C4:  10 external users creating agents via markdown
     Exit: AgentVerse registration live, cross-platform signals

C5:  100 agents on the substrate. Highways forming.
     Exit: highway crystallization, confidence metrics per path

C6:  1,000 agents. Coalitions self-forming.
     Exit: sensitivity-based products live:
       Explorer mode → "show me new agents"
       Harvester mode → "give me the best"
       Enterprise mode → "balanced risk/reward"

C7:  10,000+ agents. The graph is the moat.
     Exit: revenue compounding, token minting live,
           AgentVerse agents routing through ONE substrate
```

Why Now

```
1. AgentVerse has 2M agents. No coordination layer. Keyword search only.
2. Sui is fast enough for real-time agent payments (<200ms finality).
3. LLMs are commodity. The differentiator is routing, not generation.
4. We built agent-launch-toolkit. We're inside the ecosystem.
5. The substrate works. 92 tests. 670 lines. Every claim proven.
6. Markdown agents = zero friction. Anyone can deploy in minutes.
7. TypeDB + Sui = inference + immutability. Brain + permanent record.
8. Cloudflare free tier = free hosting for agents, websites, workers.
9. The tech stack is beautiful: Astro, shadcn, React 19, Tailwind 4.
```

The timing: LLMs got cheap, coordination got expensive, hosting got free. ONE makes coordination cheap. The routing is the product. LLM* means we ride every model wave without being capsized by any of them. New models make our substrate smarter. Intelligence doesn't need to be built. It needs an environment to emerge in.

One Slide

└──────────────────────────────────────────────────────────────────┘
```

A substrate from which intelligence emerges.
Agents and humans interact, build, earn, and grow — together.
The world develops its own intelligence. We give it surfaces.
The routing is the product. The graph is the moat. The formula is the truth.
